Supplementary material

Forty-six popular publicly available datasets in Table I are employed to evaluate the proposed algorithm. The MIFCM and TIEB are compared to the proposed method. Additionally, another two groups of ensemble algorithms have also been adopted as the comparison algorithms. The first group comprises eight classical ensemble algorithms: RUSBoost(RBO), SMOTEBoost(SBO), UnderBagging(UBAG), SMOTEBagging(SBAG), BalancedBagging(BBAG), EasyEnsemble(EYEE), BalanceCascade(BACE), GBDT. Each one of these methods represents a distinct combination of an ensemble method (e.g., bagging, boosting and hybrid method). For comparison with more sophisticated algorithms, the second group uses six state-of-the-art ensemble algorithms: CBIS, SPE, EASE, HOEC, HD-Ensemble, Imbalance-XGBoost.

Decision tree C4.5 was adopted as the base classifier in the experiment. 5-fold cross validation procedure (5-CV) was adopted and the 5-CV procedure was repeated 10 times on every experimental dataset to eliminate the effect of randomness.

Evaluation Metrics and Parameter Setting

To assess the performance of the methods, this paper used AUC, F-measure (F-M), G-mean (G-M), Matthews correlation coefficient (Mcc) criteria. Moreover, the nonparametric statistical test methods were adopted to detect statistical differences between all the methods.

For the proposed method, three parameters need to be determined before running the learning procedure: (1) ρ , as defined in Eq.(3), which determines the number of subsets, (2) K, which means the number of nearest neighbor samples for SNC, (3) L, which is used to determine the number of layers for DSEN-LG. $\rho=1, K=3, L=3$ in this paper. In SIFCM, the difference in the number of samples before and after clustering is set to 1, the fuzzification coefficient m=2 and $\varepsilon=10^{-5}$. In LGSCM, $\sigma=0.01, \lambda=\lambda_1=1$ and the Gaussian kernel function $k\left(x_i,x_j\right)=\exp(-\left\|x_i-x_j\right\|^2/2\gamma^2)$ was used in the study, where $\gamma=1.2$. All the results are obtained under this setting. For all compared methods except CBIS, HOEC and HD-Ensemble, the number of the base classifiers are set to $\lfloor IR \rfloor$. For SMOTEBoost, SMOTEBagging, the number of neighbors is set to 3. For SPE, the number of bins is assigned 20 as to the original paper. For Imbalance-XGBoost, the focal loss is used and focal_gamma = [1.0,1.5,2.0,2.5,3.0] following the original paper. Other parameters are default.

Verification of DSEN-LG by Ablation Method

To demonstrate the effectiveness of deep envelope samples obtained by DSEN-LG, ablation method was adopted to compare the proposed algorithm with the MIFCM and TIEB. Table II is the comparison results between the TIEB, MIFCM and proposed DSEN-LGIE. TIEB denotes the traditional imbalanced ensemble methods with bagging. MIFCM means the original dataset is clustered by MIFCM. From Table II, the proposed algorithm shows a large improvement in performance on all four metrics compared to MIFCM and TIEB method for most datasets. This indicates envelope samples generated through DSEN-LG network are of high quality and very effective. The DSEN-LGIE is better than the TIEB. It means that the multilayer clustering can obtain envelope samples with high-quality, which are more helpful for imbalanced learning. The DSEN-LGIE is better than the MIFCM. It means that the LGSCM can well enhance the consistency of the interlayer samples of MIFCM, thereby contributing to improving the quality of the envelope samples.

Fig.6 compared intuitively the envelope samples' distribution generated by the proposed algorithm and the original samples' distribution of the compared algorithms SPE, EASE and Imbalance-XGBoost on Ecoli1. It can be seen the envelope samples are more separable than the original samples.

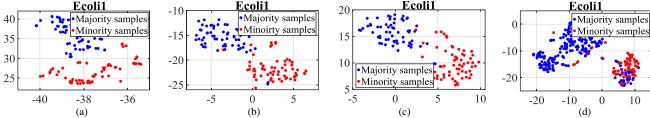

Fig.6. Sample distribution with different algorithms for Ecoli1: (a) is the envelope samples distribution with DSEN-LGIE; (b) is the original samples distribution with SPE; (c) is the original samples distribution with EASE; (d) is the original samples distribution with Imbalance-XGBoost. The envelope samples are more separable than original samples

Besides, four diversity indicators such as Disagreement(dis), Correlation coefficient(ς), Q-statistic, and Kappa (κ) are applied to measure the diversity of base classifiers. Higher values of dis are associated with higher diversity, and, conversely, smaller values of ς , Q-statistic, κ are associated with higher diversity. Table III records the results of four diversity indicators on Ecoli3 and Yeast1458vs7 obtained using DSEN-LGIE, BBAG, SBAG and UBAG, and Kappa-AUC, F-M, G-M and Mcc diagrams are designed in Fig.7. From Table III, it can be observed that DSEN-LGIE got better scores on each indicator. That is, DSEN-LGIE has higher diversity. In the Fig.7, it can also be seen the points obtained by DSEN-LGIE are located in the upper left corner of the figure. It means the kappa values are smaller and AUC, F-M, G-M and Mcc values are higher with the proposed algorithm, indicating the base classifiers of the proposed algorithm have higher diversity and higher performance than other imbalanced ensemble methods.

TABLE III DIVERSITY ANALYSIS OF BASE CLASSIFIER

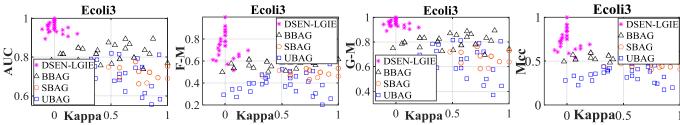

Fig.7. Diversity and performance analysis of base classifiers performance for Ecoli3.

Table III shows the high diversity of base classifier in DSEN-LGIE. The base classifiers are constructed based on the envelope samples and the final prediction results through the voting mechanism. Except for the diversity of base classifiers, Table IV discusses the predictive accuracy of the base classifiers for minority samples in DSEN-LGIE and TIEB for dataset 'Ecoli1'. The sample number (SN) for the minority samples is '1-16', and the actual labels (AL) for the minority samples are '0'. The number of basic classifier (BC) is 3 and the prediction fusion (PF) of three basic classifiers can be obtained by voting mechanism. As shown in Table IV, for the sample 12, the first base classifier (BC1) prediction is inconsistent with the actual label (AL), however, the labels of base classifier 2 (BC2) and base classifier 3 (BC3) are predicted correctly to realize error correction. Similarly, for the samples 14, 15 and 16, the second base classifier prediction is inconsistent with the actual label, but the base classifier 1 and 3 predicted correctly to realize error correction. The proposed algorithm guarantees both high prediction accuracy and diversity of base classifiers. However, for traditional method, the diversity is limited.

Comparison with Classical Imbalanced Ensemble Methods

Tables V lists the average AUC, F-M, G-M and Mcc values obtained by classical imbalanced ensemble methods and proposed DSEN-LGIE method. It can be seen an overwhelming improvement of DSEN-LGIE over the other imbalanced ensemble methods on all four criteria. In particular, when considering AUC and G-M, it is observable the method proposed in this paper provided the best performance on 40 and 39 datasets respectively, and never showed the worst performance on any dataset. For F-M and Mcc, the proposed method provided the best performance on 29 and 31 datasets respectively. Thus, DSEN-LGIE perform best in most imbalanced datasets.

Assuming the first rank for the method with the best performance and the ninth rank for the method with the worst performance, so for AUC, F-M, G-M and Mcc, the average ranks of each method on the experimental datasets can be calculated and analyzed. Table VI gives the average ranks of AUC, F-M, G-M and Mcc of each method on the 46 datasets. Table VI shows the proposed DSEN-LGIE method achieves the lowest average ranks. So the performance of proposed method is the best.

TABLE VI AVERAGE RANKS OF ALL COMPARED ENSEMBLE METHODS

Algorithm	AUC	F-M	G-M	Mcc
DSEN-LGIE	1.500	2.717	1.630	2.326

Whether there were the statistically significant differences with other imbalanced ensemble methods in terms of average ranks was analyzed, the results of Holm's test are recorded in Table VII. In the Holm's test, the proposed method was taken as the control method, and the level of significance is α/n_c , where $\alpha=0.05$ and n_c is the number of comparisons between algorithms. The results of Holm's test are recorded in Table VII. From Table VII, It's obvious that all the hypothesis of equivalence have been rejected, indicating the proposed method DSEN-LGIE performs better than the other imbalanced ensemble methods significantly. The results indicate that the deep envelope samples generated by DSEN-LG are more competitive.

Comparison with State-of-the-art Imbalanced Ensemble Methods

Table VIII records comparison results between the proposed DSEN-LGIE method and six state-of-the-art imbalanced ensemble methods. The comparisons in Table VIII clearly demonstrated that the proposed DSEN-LGIE provide better performance in terms of the four metrics than compared methods, suggesting that DSEN-LGIE generates high-quality and high- separability envelope samples.

To verify the statistically significant difference between the methods, Wilcoxon paired signed-rank test was adopted, and six comparisons DSEN-LGIE vs CBIS, DSEN-LGIE vs HD-Ensemble, DSEN-LGIE vs EASE, DSEN-LGIE vs HOEC, DSEN-LGIE vs SPE and DSEN-LGIE vs Imbalance-XGBoost were tested. Table IX records the results. In Table IX, R+ is the sum of ranks for the datasets in which the first algorithm outperforms the second algorithm and R- is the sum of ranks for the second algorithm outperforms the first algorithm. It can be found R+ is always larger than R-, and all P-values are smaller than 0.05. P-value <0.05 means the hypothesis of equivalence in six comparisons were rejected. Thus, it can be stated that DSEN-LGIE is clearly better than the six state-of-the-art imbalanced ensemble methods.

Parameter Analysis

visualize the effects of three parameters ρ, K, L on the performance DSEN-LGIE. Let $\rho = 0.5, 0.6, 0.7, 0.8, 0.9, 1$, K = 0,1,2,3,4,5. Four datasets which represented two types of datasets are chosen (e.g., high- and low-IR), including Ecoli2, Ecoli3, Yeast1458vs7 and Yeast5. As depicted in Fig.8, the performance of DSEN-LGIE on the four datasets increases when ρ increases. The possible reason is that SG is performed based on feature weighting, rather than random sampling or clustering. It ensures that the majority class samples in each subset are different, so an increase in ρ ensures that more majority class samples are used for training. For K, L, the performance of DSEN-LGIE on the four datasets increases in the preliminary stage. K = 0, L = 0 mean there are no SNC and multilayer sample transformation, and the increase of algorithm performance in the preliminary stage further illustrates the effectiveness of proposed DSEN-LG network. After K, L reach a certain value, the performance of DSEN-LGIE decreases. The possible reason is that a large K can lead to an increase in the dimensionality of the envelope sample and thus cause dimensional redundancy, which causes poor performance and if L is too large, poor quality deep envelope samples will be generated due to the fact that the high-layer samples contain less information. In summary, ρ could be selected between 0.7 and 1, K could be selected between 1 and 4, L could be selected between 3 and 6 considering four criteria.

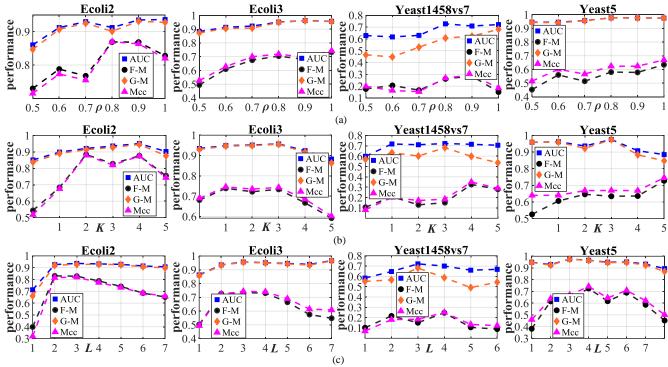

Fig. 8. Performance with different parameters on the DSEN-LGIE: (a) is for different ρ , (b) is for different K, (c) is for different L
